210C-PS4

I worked with zorah on the analytical parts + Jack Grace Ahand for the code 1. a) Guess:

=) 
$$n_{ya} = \frac{-\sigma n_{\pi a} (\phi_{\pi} - \rho_{a})}{1 - \rho_{a}}$$

$$\mathcal{I}_{Y\alpha} = \left[\frac{K[\gamma_{Y\alpha} - \frac{1+p}{\sigma+p}]}{1-p_{\alpha}}\right] \left[\frac{-\sigma(\phi_{\pi}-p_{\alpha})}{1-p_{\alpha}}\right] = \mathcal{I}_{Y\alpha}\left[1 + \left(\frac{\sigma(\phi_{\pi}+p_{\alpha})}{1-p_{\alpha}}\right)\left(\frac{K}{1-p_{\alpha}}\right)\right] = \frac{\sigma K\left(\frac{1+p}{\sigma-p}\right)\left(\phi_{\pi}-p_{\alpha}\right)}{\left(1-p_{\alpha}\right)\left(1-p_{\alpha}\right)}$$

plug back in to get 2 Ta

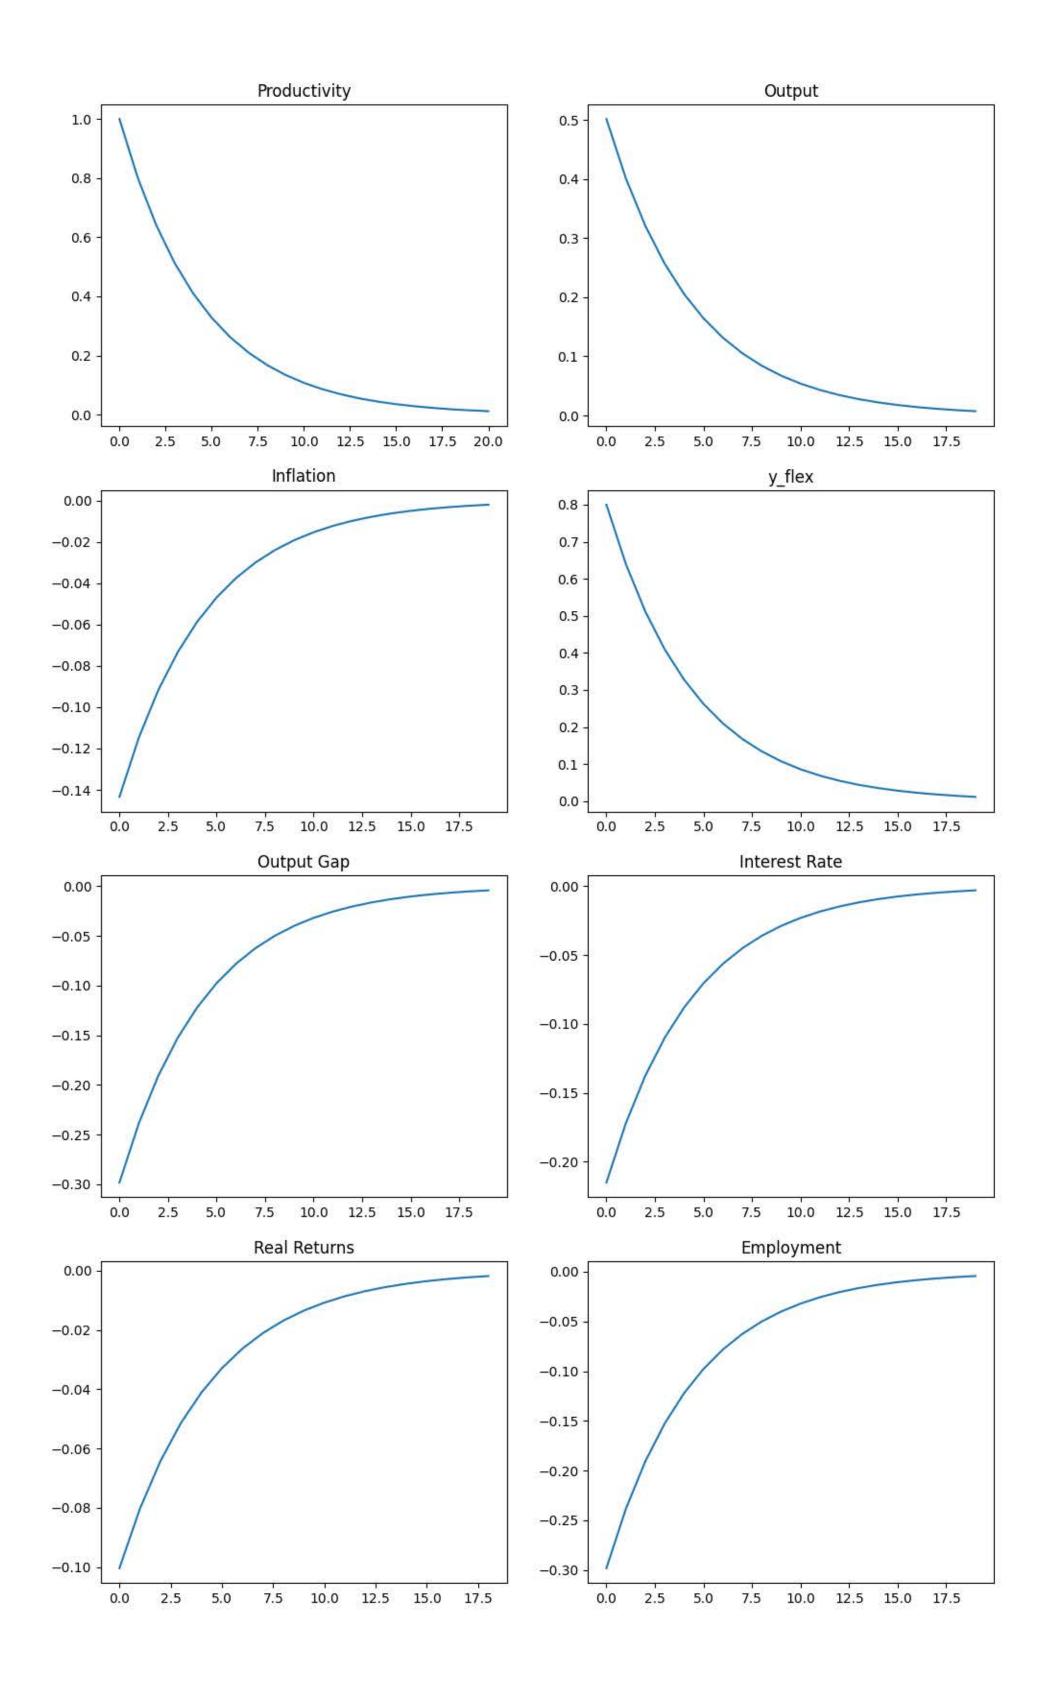

## b) see affacted

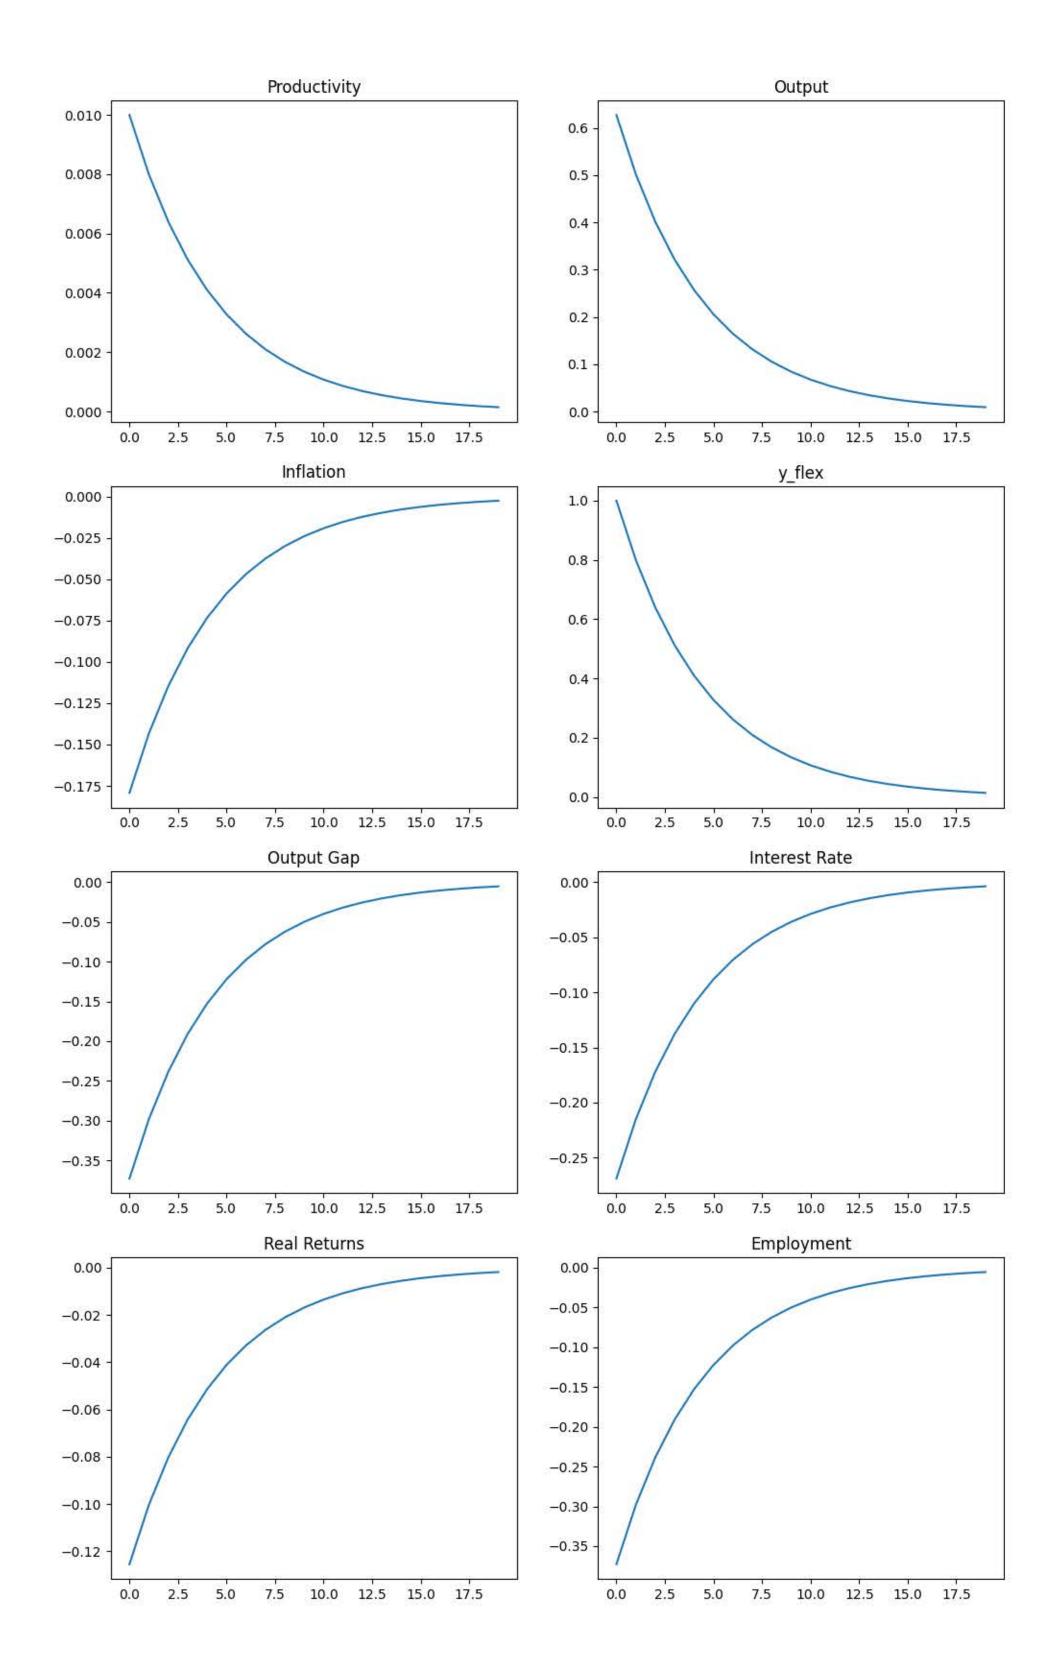

c) A shock to productivity increases output and also decreases labor which makes sense from the firm's perspectue since they can produce more with less input.

The optimal y (y-flex) also increases since it is optimal to produce more with higher productivity. The output gap temporarily decreases since firms cannot adjust as they would optimally.

Interest rates and real returns decrease since firms can lower prices: and the central back responds through the taylor rule.

d) See attacked

7. 2) The equation is not recording Since some would need 
$$\frac{f^*}{f^*}$$
 on the left  $a_{m-1}$  of  $\frac{f^*}{f^*}$  on the right  $a_{m-1}$  of  $\frac{f^*}{f^*}$  on the right  $a_{m-1}$  of  $\frac{f^*}{f^*}$  on the right  $a_{m-1}$  of  $\frac{f^*}{f^*}$  of  $\frac{f^*}{f$ 

e) If  $p_{*}^{*} > 1$  that means the optimal price relative to the price the firm is actually charging is high. Since the current price level is a combination of previous prices and  $p_{*}^{*}$ , prices are grown when  $p_{*}^{*} > p_{*}^{*}$  so inflation will also be >1.

2. f) + g) see attached

SS cales:

Normalize Y=1, A=1Let V=1  $Q = \frac{1}{\beta} \left(\frac{\beta}{\beta}\right)^{\frac{1}{\beta}} \cdot 1 \Rightarrow Q = \frac{1}{\beta}$   $A = A \left(\frac{\beta}{\beta}\right)^{-1} = B$   $A = A \left(\frac{\beta}{\beta}\right)^{-1} = B$ 

Y=AN=)N=1 C=Y=)C=1  $W|p=\frac{XN^{\varrho}}{C+\delta}=\frac{XY^{\varrho}}{Y+\delta}=X$   $F_{2}=Y+\theta\Lambda\Pi^{2}+F_{2}=)F_{2}=\frac{Y}{(1-R\theta)}=\frac{1-R\theta}{1-R\theta}$   $F_{1}=(1+M)YW|P+\theta\Lambda\Pi^{2}F=F=)F_{1}=\frac{(1-R\theta)}{1-R\theta}$ 

(Not sure what it would mean to have an IRF for markup?)

h) When & is higher, trices are more sticky.

As such, the output gap is much larger when to is higher, Similarly, N will adjust since prices connot adjust in response to greater productivity.

Consumption and output are sticker when p is structurer since demand is not responsive to the change in productivity.

Interest rates and inflation are also less responsive when A is higher since prices cannot move in response to the change in productivity.

i) In the RBC motel since prices aren't stroky, I and C can adjust perfectly in response to a change in a. Resultingly there will be no output gap. The case as \$100 is most similar to the RTSC. Without market power, firms in RBC cannot sustain markups
